\textbf{1. Introduction}

Polynuclear clusters of paramagnetic 3d metal ions have attracted intense interest in the last two decades for a number of reasons including their novel crystal structures and magnetic properties [1–4]. Such compounds often exhibit impressive crystal structures with unique features such as high nuclearities and aesthetically pleasing, high symmetry structural cores [1]. In addition they sometimes display interesting magnetic properties including the presence of ferromagnetic exchange interactions that lead to large or even abnormally large spin ground state values [2–7]. The construction of molecular aggregates possessing large \(S_T\) values has been a challenge for synthetic chemists since they are related to interesting phenomena and hot research areas such as single molecule magnetism [2–4] and magnetic refrigeration [8].

The most successful synthetic methods towards metal clusters exhibiting large \(S_T\) values include the use of ligands that usually lead to ferromagnetic exchange interactions [9] or the employment of ligands and synthetic procedures that lead to complexes that are known to display ferromagnetic exchange interactions [10]. One family of compounds that has attracted intense interest because of their high symmetry structural core and the fact that they usually exhibit entirely ferromagnetic exchange interactions are those containing the decametallic supertetrahedral core. A Cambridge database search for decametallic discrete Mn complexes exhibiting the \{\text{Mn}_{10}\{\text{μ}_4\text{-O}\}_6\}^{18+} supertetrahedral core gave twelve hits and a second one for all compounds containing this core even as fragment or repeating unit of multidimensional coordination polymers returned over thirty hits [6,7,11–26]. The extended appearance of this core in Mn carboxylate chemistry reveals not only its significance for this area but also its ability to be stabilized with a series of chelating ligands. The most widely appeared ligands in decametallic
supertetrahedral compounds are various aminoalcohols [11–14],
diols [7,16,17,19,20,22–26] and triols [6,17], although such com-
ponents have been stabilized with a variety of ligands including
oxacalix[3]arene [18], benzotriazole [21], etc. Intense interest has
attracted the most commonly appeared [MnIII₂MnIV₆(µ-O)₄]¹⁸⁻
supertetrahedral core since it usually displays entirely ferromagnetic
exchange interactions and the maximum possible spin ground state
value Sₚ = 22. Interestingly, members of this family displayed
enhanced magnetostructural effect and were proposed for use in
magnetic refrigeration applications [11,12]. In addition, this
core has appeared as fragment in high nuclearity [MnP₇] [7] and
[Mn₁₉] [6] clusters which consist of two edge- or vertex-sharing
[MnIII₆MnIV₄(µ-O)₄]¹⁸⁻ sub-units respectively. The exchange in-
teractions within these clusters are entirely ferromagnetic resulting
in giant Sₚ values of 37 ([MnP₇]) and 83/2 ([Mn₁₉]) which correspond
to the highest Sₚ value reported for a SMM and the second highest
Sₚ value for any metal cluster in general, respectively. Furthermore,
this core has also appeared as fragment in nanosized homometallic
and heterometallic aggregates including the giant [MnP₉] cuboctahe-
dron consisting of eight tightly connected [MnIII₆MnIV₄(µ-O)₄]
¹⁸⁻ supertetrahedral sub-units [24] and a [Mn₉Na₄]‘loop-of-loops-
and two [MnIII₆MnIV₄(µ-O)₄]¹⁸⁻ supertetrahedra. These compounds
display dominant ferromagnetic exchange interactions leading to
large Sₚ values (61/2 in the case of [MnP₉] aggregate and 26 in the case
of [Mn₉Na₄] complex). The presence of decametallic supertetrahedra
in the repeating units of multidimensional coordination polymers has also been realized with the list of such species containing compounds based on a [MnIII₆MnIV₄(µ-O)₄]¹⁸⁻
and a [MnIII₆MnIV₄(µ-O)₄]²⁺ repeating units [7,16,23]. Apart from
the rather common [MnIII₆] oxidation state level, the decametal-
supertetrahedral core has also appeared at the [MnIII₆MnIV₆] [18–20]
and [MnIII₆] [21] ones. In addition, the heterometallic [MnIII₆MnIV₆(µ-O)₄]
(M = any metal ion) supertetrahedral core, has also appeared only once in discrete form in a MnIII₂CeIII₄ cluster
[27]. It has also been observed a few times as a fragment in high nuclearity [MnIII₆DyIII₄] [28] and [MnIII₆MnIII₆] (M = DyIII, YIII, LuIII, SfIII
and CeIII) [29,30] aggregates consisting of two edge- or vertex-sharing
decametallic supertetrahedra, respectively and in the nanosized
[Mn₉₂Na₄] aggregate containing four edge-sharing [MnIII₆MnIV₄Na₄]
supertetrahedral repeating units [24]. Herein we report the synthesis, structural, spectroscopic and magnetic characterization of two new compounds, a homometallic [MnIII₆MnIV₄(µ-O)₄(µ-O-Me)₉]₂(btH)₂(edH)(PhCO₂)₆\)
(substituted (1 6H₂O) (btH = (±)-1,2,4-butanetiol; edH₂ = 1,2-ethanediol)
and a heterometallic [MnIII₆CaII(µ-O)₄(µ-O-Me)₉]₂(btH)₂(edH)(PhCO₂)₆\)
(2) (pH₂ = 1,3-propanediol) one, exhibiting supertetrahedral structural
cores. Core 1 displays an unprecedented in the rich family of
Mn-based decametallic supertetrahedra [MnIII₆MnIV₄] oxidation state level whereas complex 2 is a unique heterometallic analogue of the
family of complexes containing the [MnIII₆MnIV₄(µ-O)₄]¹⁸⁻ core in
which the MnIII ions are replaced by CaII ions. Magnetism studies
revealed the presence of dominant ferromagnetic exchange interactions in 1 leading to large Sₚ = 23/2 and entirely ferromagnetic exchange interactions in 2 affording an Sₚ = 12.

2. Experimental

2.1. General and physical measurements

All manipulations were performed under aerobic conditions
using materials (reagent grade) and solvents as received.
[MnO₆(O₂CPh)₉(py)₉(H₂O)] was prepared as described elsewhere [31].
Microanalyses (C, H, N) were performed by the in-house facili-
ties of the University of Cyprus, Chemistry Department. IR spectra
(4000–400 cm⁻¹) were recorded on a Shimadzu Prestige-21 spec-
trometer with the samples prepared as KBr pellets. Variable-tem-
perature dc and ac magnetic susceptibility data were collected at
the University of Florida using a Quantum Design MPMS-XL SQUID
superconductometer equipped with a 7 T magnet and operating in the
1.8–300 K range. Samples were embedded in solid eicosane to pre-
vent torquing. The ac magnetic susceptibility measurements were
performed in an oscillating ac field of 3.5 G and a zero dc field. Pasc-
als’s constants were used to estimate the diamagnetic corrections,
which were subtracted from the experimental susceptibilities to give
the molar paramagnetic susceptibility (xM).

2.2. Compound preparation

2.2.1. [MnIII₆MnIV₄(µ-O)₄(µ-O-Me)₉]₂(btH)₂(edH)(PhCO₂)₆\)
A colorless solution of btH₂ (0.095 ml, 0.11 g, 1.06 mmol) in
MeOH (5 ml) was added to a brown solution of [MnO₂(C₈H₈)₉]
(py)₉(H₂O)] (0.20 g, 0.18 mmol) in MeOH (10 ml) and to the result-
ting brown slurry was added solid NaOCN (0.72 mmol). The
reaction mixture was left under magnetic stirring for 40 min and
the resulting brown slurry was added solid NaOCl (0.047 g, 0.72 mmol).
The reaction mixture was left under magnetic stirring for 40 min and
the resulting solution remained undisturbed for 15 min. Then it
was filtered off and the filtrate was left to slowly evaporate at room
temperature. After a few weeks X-ray quality crystals of 1 3H₂O
were formed. The reaction yield was 20% based on total Mn con-
tent. The dried solid was analyzed as 1·H₂O. Anal. Calc.: C, 37.21; H, 4.31. Found: C, 36.92; H, 4.38. IR (KBr, cm⁻¹): 3119b, 2848w, 1638s, 1816s, 1570 m, 1400s, 1105 m, 1036 m, 947w, 777w, 718s, 679 m, 625 m, 561 m, 480m.

2.2.2. [MnIII₆CdII(µ-O)₄(µ-O-Me)₉]₂(btH)₂(edH)(PhCO₂)₆\)
A colorless solution of btH₂ (0.15 ml, 0.16 g, 2.1 mmol) and solid
CdCl₂·4H₂O (0.09 g, 0.5 mmol) were added to a solution of
MnCl₂·4H₂O (0.10 g, 0.5 mmol) in MeCN/MeOH (25/4 ml). The resulting orange slurry was gently heated for 1 h under stirring during which time it turned to a brown solution. The latter was filtered off and the filtrate left to stand undisturbed in a closed flask. After five days, X-ray quality, orange, rod-shaped crystals of 2 were observed. The crystals were collected by filtration, washed with cold MeCN and dried on air. The reaction yield was 40% based on total Mn content. The dried solid was subjected satisfactorily as 2. Anal. Calc.: C, 21.96; H, 5.00. Found: C, 21.68; H, 5.21. IR (KBr, cm⁻¹): 3218b, 2915w, 2882w, 1564 s, 1522 m, 1481 s, 1475 s, 1304 m, 1269 m, 1253w, 1224 m, 1196 m. .

2.3. Single-crystal X-ray crystallography

Data were collected on a SuperNova A Oxford Diffraction diffractometer, equipped with a CCD area detector and a graphite monochromator utilizing Cu-Kα (λ = 1.54184 Å) and Mo Kα radiation (λ = 0.71073 Å) for 1·3H₂O and 2, respectively. Suitable crystals covered with paratone-N oil were mounted on the tip of glass fibers or scooped up in cryo-loops at the end of a copper
pin and transferred to a goniostat where they were cooled for data collection. Empirical absorption corrections (multi-scan based on symmetry-related measurements) were applied using CRYSALIS RED software [32]. The structures were solved by direct methods with SIR92 [33] and refined on F² using full-matrix least squares with SHELXL97 [34]. The program SQUEEZE [35], a part of the PLATON package of crystallographic software, was used to remove contribution of highly disordered solvent molecules in 1 3H₂O. Software packages used: CrysAlis CCD for data collection [32], CrysAlis RED for cell refinement and data reduction [32], WINGX for geometric calculations [36], and DIAMOND [37] for molecular graphics. The non-H

atoms were treated anisotropically, whereas the hydrogen atoms were placed in calculated, ideal positions and refined as riding on their respective carbon atoms. In compound 1, the H atoms of the alcohol O atom of the organic ligand btH$_2$ and these of the H$_2$O solvent molecules could not be located. The H atoms of one independent pd$_2$-ligand (totally two in the molecule) and the alcohol O atom of terminal MeOH molecules could not be located in the molecule of 2. Unit cell data and structure refinement details for compounds 1-3H$_2$O and 2 are listed in Table 1. Full details can be found in the CIF files provided in Supplementary information.

3. Results and discussion

3.1. Synthesis

Our group has been investigating the use of polyols in Mn carboxylate chemistry. These investigations have focused on the use of paramagnetic or diamagnetic heterometals targeting to mixed metal compounds. Particular attention has attracted the use of diamagnetic or paramagnetic heterometals in Mn/pdH$_2$ reactions especially after the discovery of a 3-D coordination polymer based on a high-spin [Mn$_{19}$Na] repeating unit [40]. These investigations have afforded some high nuclearity clusters displaying aesthetically pleasing crystal structures and interesting magnetic properties such as a nanosized [Mn$_{40}$Na$_4$] "loop-of-loops" aggregate consisting of four [Mn$_{40}$Na$_4$] loops [41] and a [Mn$_{15}$K] loop incorporating a supertetrahedron [26]. These studies were also extended to the use of Ca$^2+$ salts in Mn/pdH$_2$ chemistry targeting to mixed Mn$^{III}$/Ca$^{II}$ clusters. Such compounds have attracted attention not only for their interesting magnetic properties and crystal structures but also because they could possibly serve as structural models of the Mn$_{37}$Ca cluster appearing in the active site of photosystem II that is responsible for the photocatalytic oxidation of H$_2$O to O$_2$ [42]. In fact, compound 2 is the initial result of these studies. Thus, the reaction of MnCl$_2$, 4H$_2$O and CaCl$_2$-4H$_2$O with pdH$_2$ in the presence of NET$_3$ in ~1:1:4:2 molar ratio in MeCN/MeOH (25/4 ml) afforded a nanosized solution which was left undisturbed in a closed flask for five days, upon which orange X-ray quality crystals of 2 were formed in 40% yield; the dried solid was analyzed as solvent free 2.

The formation of complex 2 is summarized in Eq. (2).

$$\text{6MnCl}_2 + 4\text{H}_2\text{O} + 4\text{CaCl}_2 - 4\text{H}_2\text{O} + 6\text{pdH}_2 + 10\text{MeOH}$$

$$+ 1.5\text{O}_2 \rightarrow \text{[Mn}^{III}\text{Ca}^{II})_{14}^{2+}[(\mu_4-O)]_4[(\mu_3-\text{Cl})_4[\text{pd}_{10}\text{Cl}_{2}(\text{MeOH})_{10}]]$$

$$+ 14\text{HCl} + 3\text{H}_2\text{O}$$

(2)

3.2. Description of structures

Representations of the molecular structure and the structural core of compound 1 are shown in Fig. 1 and selected interatomic distances and angles are listed in Table S1.

Complex 1-3H$_2$O (Fig. 1) crystallizes in the cubic space group Pa3 and its asymmetric unit consists of one third of the Mn$_{19}$ Na cluster and one crystallization water molecule. Its metallic skeleton consists of a mixed valent Mn$_{15}$Na$_{14}^{III}$ superoctahedron in which the Mn$^{III}$ ion occupies one of the apex positions. The oxidation states of the Mn ions [43] and the protonation levels of the O atoms [44] were determined by bond valence sum (BVS) calculations, charge considerations and inspection of metric parameters. All Mn$^{III}$ ions are hexacoordinated, displaying a distorted octahedral coordination geometry and containing the expected, for high spin d$_{5}^{0}$ ions, Jahn–Teller (JT) elongations (the JT axes are not co–parallel). The Mn$^{III}$ ion is heptacoordinated although one of the bond lengths is too long (Mn–O ~ 2.8 Å). The superoctahedron is constructed from twelve Mn$^{III}$ ions forming a 72-vertex-sharing tetrahedra. The Mn$_{15}$Na$_{14}^{III}$ superoctahedron is constructed from twelve Mn$^{III}$ ions forming a 72-vertex-sharing tetrahedra.
Mn ions in a syn,syn-η^2:η^1:μ coordination mode and through a η^2:η^1:μ ed^2− ligand bridging another pair of Mn ions. The three [MnIII(μ4−O)]^{10+} tetrahedra are held together by three μ3−OMe bridges. The Mn ions of the [MnIII,MnII(μ4−O)]^{16+} tetrahedron are connected through three η^2:η^2:η^1:μ3 brH^2− ligands occupying six of the coordination sites of the MnIII ion and connecting it to the other Mn ions of the same tetrahedron and also to Mn ions of the [MnII(μ4−O)]^{10+} tetrahedra.

Complex 1 is a new member of the extended family of the decametallic supertetrahedra possessing a [Mn_{10}(μ4−O)_4]^{10+} core. In the past several clusters displaying a decametallic supertetrahedral core either in a discrete form or as part of a high nuclearity cluster or repeating unit of a coordination polymer had been reported with various chelating ligands. These complexes exhibited the oxidation state levels [Mn^{IIII}[Mn^{III}]] [18−20], [Mn^{III}Mn^{II}] [6,7,11−17,22−25] and [Mn^{III}Mn^{II}] [21] (Fig. 2) with the [Mn^{III}Mn^{II}] one being by far the most common oxidation level shown in decametallic supertetrahedra. Interestingly, the [Mn^{III}Mn^{II}] oxidation state distribution appeared in 1 is observed for the first time in this family of [Mn_{10}] supertetrahedra.

Representations of the molecular structure and the structural core of compound 2 are shown in Fig. 3 and selected interatomic distances and angles are listed in Table S2.

Complex 2 (Fig. 3) crystallizes in the monoclinic space group C2/c and its asymmetric unit consists of half of the [Mn^{III}Ca^{2+}]^{18+} cluster. The metallic skeleton of 2 consists of a heterometallic MnIII,Ca^{2+} supertetrahedron in which the Ca^{2+} ions occupy the apex positions. The oxidation states of the Mn ions [43] and the protonation levels of the O atoms [44] were determined by bond valence sum (BVS) calculations, charge considerations and inspection of metric parameters. All Mn^{III} ions are hexacoordinated, displaying a distorted octahedral coordination geometry and containing the expected, for high spin d^4 ions, JT elongation axes which are not co-parallel. The Ca^{2+} ions are either hexacoordinated (Ca1) or heptacoordinated (Ca2). The Ca^{2+} ions occupy the apex positions of a tetrahedron and the Mn^{III} ions are located in its edges. The metal ions are connected through four μ4−O^2− ions forming the [Mn^{III}Ca^{2+}(μ4−O)_4]^{18+} core (Fig. 3) which consists of four [Mn^{III}Ca^{2+}(μ4−O)]^{14+} vertex-sharing tetrahedra. In fact, the [Mn^{III}Ca^{2+}(μ4−O)_4]^{18+} core is analogous to the commonly appeared homometallic [Mn^{III}Mn^{II}(μ4−O)_4]^{18+} supertetrahedral core in which the Mn^{III} ions have been replaced by Ca^{2+} ions. The Mn^{III} ions are bridged through four μ3−Cl^− ions which occupy their JT axes. The two Ca^{2+} and one Mn^{III} ions located in each edge of the tetrahedron are connected through one pd^2− ligand (totally 6 pd^2− in 2) bridging in a η^2:η^2:μ3 mode. The peripheral ligation of the Ca^{2+} ions is completed by two terminal Cl^− ions and ten MeOH molecules. Alternatively the [Mn^{III}Ca^{2+}(μ4−O)_4]^{18+} core can be described as exhibiting an ‘octahedron subscribed in a tetrahedron’ metal topology (Fig. 3, bottom right). The inner octahedral unit is formed by the six Mn^{III} ions bridged through the four μ3−Cl^− ions whereas the outer tetrahedral unit comprises the four Ca^{2+} ions. The [Mn^{III}(μ3−Cl)_4]^{14+} and [Ca^{2+}] sub-units are connected through the four μ4−O^2− ions with each of them bridging three Mn^{III} and one Ca^{2+} ions.

Complex 2 represents a rare example of a heterometallic [Mn_{10}−M^{n+}] supertetrahedron. In fact, there have been only three types of mixed-metal supertetrahedra reported in the past, two of which appeared as fragments of high nuclearity clusters [24,27−30]. Their metallic skeletons are shown in Fig. 4 and compared to the one of complex 2. To the best of our knowledge, there is only one other discrete heterometallic supertetrahedron, a [Mn^{IIII}Ce^{IV}] aggregate [27]. In this compound the four Mn^{III} and the Ce^{IV} ions occupy the apices and the edges of the distorted supertetrahedron, respectively. The most common supertetrahedral unit, appeared as fragment of high nuclearity clusters, is the [Mn^{III}Mn^{II}M^{n+}] (M = Na^+, Sr^{2+}, Cd^{2+}, Y^{3+}, Dy^{3+}, Lu^{3+}) one in which the heterometal is located in one of the apex positions of the tetrahedron [24,29,30]. This unit has appeared in the [Mn^{III}Mn^{II}M^{n+}] (M = Sr^{2+}, Cd^{2+}, Y^{3+}, Dy^{3+}, Lu^{3+}) [29,30] aggregates consisting of two vertex-sharing...
[Mn III][Mn][M] supertetrahedra which are analogues of the high spin $S_T = 83/2$ [Mn III]Mn II aggregate [6]. A similar [Mn III][Mn II][M] (M = Na +) core was also appeared recently as a repeating unit in a Mn III octahedron subscribed in a Ca II tetrahedron. Colour code: Mn III, blue; Ca II, light green; O, red; Cl, green; C, grey. The hydrogen atoms are omitted for clarity. (Colour online.)

Fig. 3. Partially labeled representation of the molecular structure of complex 2 (top), its [Mn III][Ca II][H₂O]₄ supertetrahedral structural core (bottom, left) and the [Mn III][Ca II] metallic skeleton (bottom, right); the dashed lines connecting the metal ions in the bottom, right figure are to emphasize the description of the [Mn III][Ca II] metallic skeleton as a Mn III octahedron in a Ca II tetrahedron. Colour code: Mn III, blue; Ca II, light green; O, red; Cl, green; C, grey. The hydrogen atoms are omitted for clarity. (Colour online.)

3.3. Magnetic properties

Solid-state dc magnetic susceptibility measurements were performed on polycrystalline samples of complexes 1 6H₂O and 2, under a magnetic field of 0.1 T in the temperature range 5–300 K. The obtained data are shown as $\chi_M T$ versus $T$ plot in Fig. 5. For compound 1 6H₂O, the $\chi_M T$ value increases slowly from 34.68 cm³ mol⁻¹ K at 300 K to 40.22 cm³ mol⁻¹ K at 100 K, then rapidly to 66.89 cm³ mol⁻¹ K at 10 K and decreases slightly to 65.11 cm³ mol⁻¹ K at 5 K. For 2, the $\chi_M T$ value at 300 K is 25.55 cm³ mol⁻¹ K and increases continuously with decreasing temperature reaching to a near plateau value of ~79 cm³ mol⁻¹ K at 40–20 K and then decreases to 67.79 cm³ mol⁻¹ K at 5 K (Fig. 5). In both compounds the 300 K $\chi_M T$ value is higher than the corresponding spin-only ($g = 2$) values of 31.375 and 18 cm³ mol⁻¹ K expected for compounds consisting of 1 Mn III/9 Mn II (1 H₂O) and six Mn III (2) non-interacting ions, respectively. The shapes of the $\chi_M T$ versus $T$ curves, the increase of the $\chi_M T$ values with decreasing temperature and the higher room temperature $\chi_M T$ values than the corresponding expected spin-only values reveal the presence of dominant ferromagnetic exchange interactions in both compounds. The maximum $\chi_M T$ value at 10 K reveals that 1 6H₂O possesses a ground-state spin value of $S = 23/2$ or 21/2; the spin-only ($g = 2$) values for $S = 23/2$ and 21/2 ground states are 71.88 and 60.38 cm³ mol⁻¹ K, respectively. For compound 2, the $\chi_M T$ near-plateau value in the 20–40 K range appears to be heading for a final value of ~79 cm³ mol⁻¹ K which is very close to the spin-only ($g = 2$) value of a species with an $S = 12$ ground state (78 cm³ mol⁻¹ K), the maximum possible $S_T$ value for a complex containing 6 Mn III ions, indicating that it exhibits entirely ferromagnetic exchange interactions. The low temperature decrease appearing in the $\chi_M T$ versus $T$ plots of 1 6H₂O and 2 is due to Zeeman effects, zero-field splitting and/or weak intermolecular interactions.

The dc magnetic susceptibility data for 2 were fit to the theoretical $\chi_M T$ versus $T$ expression derived from the spin Hamiltonian appropriate for a [Mn III] octahedron (see discussion of the crystal structure of 2 and Fig. 3, bottom, right); given in Eq. (3),
$$H = -2J_{\text{ex}}(S_1 \cdot S_2 + S_3 \cdot S_4 + S_5 \cdot S_6 + S_1 \cdot S_4 + S_2 \cdot S_5 + S_3 \cdot S_6) \tag{3}$$

where $S_i$ refers to the spin of metal ion Mn$_i$ ($S_1 = S_2 = S_3 = S_4 = S_5 = S_6 = 2$), and $J_{\text{ex}}$ and $J_{\text{trans}}$ are the pairwise exchange parameters for metal ions located in neighboring and opposite positions of the octahedron, respectively; the labeling scheme employed for the Mn ions of the Mn$_{10}$ octahedron of 2 is shown in Fig. S1 in the Supplementary information. The eigenvalues of Eq. (3) are given in Eq. (4), where $S_x = S_1 + S_5, S_y = S_2 + S_6, S_z = S_3 + S_4$, and $S_t = S_x + S_y + S_z$; $S_t$ is the resultant spin of the complete molecule:

$$E(S_t) = -J_{\text{trans}}[S_t(S_t + 1) - S_x(S_x + 1) - S_y(S_y + 1) - S_z(S_z + 1)] \tag{4}$$

We note that constant terms contributing equally to all states have been omitted from Eq. (4). An expression for the molar paramagnetic susceptibility, $\chi_m$, was derived using the above and the Van Vleck equation, and assuming an isotropic g tensor. The derived magnetic susceptibility, $\chi_m$, was obtained with

$$\chi_m = \frac{D}{N} \frac{\mu_B^2}{\pi} \sqrt{3} \frac{J_{\text{trans}}}{g \mu_B}$$

The first excited state is a triply degenerate set of $S$ states, where $S = 12, 4, 4, 4$ is the $|12, 4, 4, 4|$ state in which all six Mn III spins are aligned parallel. The second excited state is a set of $S$ states, appearing at lower temperatures. A good quality fit was obtained and the g factor. Only data for the 20–300 K range were used, since the model does not incorporate ZFS and other minor effects appearing at lower temperatures. A good quality fit was obtained (represented from the solid line of Fig. 5) with fit parameters of $J_{\text{ex}} = 3.8 \pm 0.2$ cm$^{-1}$, $J_{\text{trans}} = 1.2 \pm 0.8$ cm$^{-1}$, and $g = 2.02 \pm 0.002$, with temperature independent paramagnetism (TIP) held constant at $600 \times 10^{-6}$ cm$^3$ mol$^{-1}$. The fit indicates that [Mn$_{10}$Ca$_2$] complex has an $S_t = 12$ ground state. In the notation $|S_t, S_x, S_y, S_z|$ this is the $|12, 4, 4, 4|$ state in which all six Mn III spins are aligned parallel. The first excited state is a triply degenerate set of $S_t = 11$ states comprising the $|11, 3, 4, 4|$, $|11, 4, 3, 4|$, and $|11, 4, 4, 3|$ states at 366 cm$^{-1}$ above the ground state. Thus, the $S = 12$ ground state is well isolated from the nearest excited state.

Given the size of the [Mn$_{10}$] cluster of 1·6H$_2$O, and the resulting number of inequivalent exchange constants, it was not possible to apply the Kambe method to determine the individual pairwise Mn$_i$ exchange interaction parameters. We concentrated instead on obtaining additional information for the ground-state spin, $S_t$, and the zero-field splitting parameter, D, of 1·6H$_2$O and 2 by performing magnetization versus dc field measurements at applied magnetic fields and temperatures in the 1–70 kG and 1.8–10 K ranges, respectively. The data for complex 1·6H$_2$O and 2 are shown in Fig. 6 as reduced magnetization ($M(N_{\text{mol}})$ vs $H/T$) plots, where $M$ is the magnetization, $N$ is Avogadro’s number, $\mu_B$ is the Bohr magneton, and $H$ is the magnetic field. The $M(N_{\text{mol}})$ vs $H/T$ data were fit using the program MAGNET to a model that assumes that only the ground state is populated at these temperatures and magnetic fields, includes isotropic Zeeman interactions and axial zero-field splitting ($D^2 S_z^2$), and incorporates a full powder average. The corresponding spin Hamiltonian is given by Eq. (5):

$$H = D S_z^2 + g \mu_B H S_z - H$$

where $D$ is the axial ZFS parameter, $S_z$ is the easy-axis spin operator, $\mu_B$ is the magnetic permeability, and $H$ is the applied field. The last term in Eq. (5) is the Zeeman energy associated with an applied magnetic field. The variable-field variable-temperature magnetization data for 1·6H$_2$O were fitted when low field data, up to 1 T, were used to minimize problems arising from the presence of low-lying excited states as has been reported for other high nuclearity Mn clusters. [24–26] The best fit for 1 is shown as the solid lines in Fig. 6, top and was obtained with $S = 23/2, g = 1.94$, and $D = -0.048$ cm$^{-1}$. Alternative fits with $S = 21/2$ and 25/2 were also achieved with fit parameters $g = 2.04$ and $D = -0.053$ cm$^{-1}$ and $g = 1.93$ and $D = -0.062$ cm$^{-1}$, respectively. The different possible fits of the magnetization data are assigned to the large number of low-lying excited states which is a general property in high nuclearity Mn clusters with high S values. [24,25] For complex 2, a satisfactory fit was obtained using all data up to 7 T. This indicates that its ground state is relatively well-isolated from the nearest excited states, as suggested from the obtained fit of the variable temperature magnetic susceptibility data (vide supra). The best fit shown as the solid lines in the reduced magnetization ($M(N_{\text{mol}})$ vs $H/T$ plot) in Fig. 6, bottom was obtained with $S = 12, g = 2.07$, and $D = -0.051$ cm$^{-1}$. It is recognized that the g value is too high, however this fit is a rough estimate mainly for the S and D values of the compound which in this case are realistic. Note that the D values determined for 1 and 2 are very small being in line with the reported D values of known Mn superoctahedra [11–14,16,20]. More accurate information for the g values could be obtained using other techniques; such investigations however, are beyond the scope of this paper. 

Ac magnetic susceptibility studies at zero dc field and 3.5 G ac field were also carried out. Ac susceptibility studies are a powerful complement to dc studies for determining the ground state of a system, because they remove the complications arising from the presence of a dc field. The obtained in-phase $\chi'_{ac}$ signal for...
complexes \(\text{1â€“6H}_2\text{O}\) and 2 are plotted as \(\chi'_M/T\) versus \(T\) in Figs. S2 and S3 in the Supplementary information. The \(\chi'_M/T\) value for \(\text{1â€“6H}_2\text{O}\) increases with decreasing temperature from 15 K to 10 K and then it remains stable before it decreases at \(\approx 5\) K. Extrapolation of the \(\chi'_M/T\) data from the plateau (\(\approx 6\)–9 K) to 0 K, at which point only the ground state will be populated, gives a value of \(\approx 70\) cm\(^3\) mol\(^{-1}\) K\(^{-1}\) consistent with an \(S = 23/2\) assuming a \(g\) value slightly less than two. Thus, based on the conclusions arising from the various types of dc and ac magnetic measurements it is suggested that complex \textbf{1} exhibits a spin ground state value \(S_T = 23/2\). The \(\chi'_M/T\) value for \textbf{2} decreases slightly from 15–5 K as expected for a compound exhibiting a well-isolated ground state and then more rapidly below 5 K. Extrapolation of the \(\chi'_M/T\) versus \(T\) plot from \(T > 6\) K to avoid phenomena appearing at lower temperatures gives a value of \(\approx 78\) cm\(^3\) mol\(^{-1}\) K\(^{-1}\), which is consistent with an \(S = 12\) ground state, in excellent agreement with the findings from variable-field variable-temperature magnetization and variable temperature magnetic susceptibility studies. We thus conclude that complex \textbf{2} does have an \(S_T = 12\) ground state. Finally, complexes \textbf{1} and \textbf{2} do not exhibit any out-of-phase ac magnetic susceptibility signals down to 1.8 K.

4. Conclusions

The initial use of triol btH\(_3\) in Mn carboxylate chemistry and the extension of our investigations on the employment of pdH\(_3\) on the synthesis of mixed metal Mn/M clusters afforded a homometallic Mn\(_{10}\)Mn\(_{2}\) cluster and a heterometallic Mn\(_{2}\)Ca\(_{2}\) aggregate. Compounds \textbf{1} and \textbf{2} exhibit [Mn\(_{10}\)Mn\(_{2}\)(btH\(_3\))\(_4\)]\(^{2+}\) and [Mn\(_{2}\)Ca\(_{2}\)(btH\(_3\))\(_4\)]\(^{18+}\) supertetrahedral structural cores, respectively being members of an extended family of metal complexes combining high symmetry crystal structures and interesting magnetic properties. In particular Mn supertetrahedra often display ferromagnetic exchange interactions and the maximum possible spin ground state values. In fact this family includes members displaying giant \(S_T\) values such as \(3/2\), \[6\] 37, \[7\] 61/2, \[24\] 26 \[25\] and 22 \[12â€“14,16,17\]. Interestingly, complex \textbf{1} displays a Mn\(_{10}\)Mn\(_{2}\) oxidation state level that appears for the first time in the rich family of homometallic [Mn\(_{10}\)] supertetrahedra. In addition, complex \textbf{2} displays a core related to the common [Mn\(_{10}\)Mn\(_{2}\)(btH\(_3\))\(_4\)]\(^{18+}\) supertetrahedral one in which the four Mn\(_{2}\) ions are replaced by Ca\(_{2}\) ions. This heterometal ion distribution has not appeared again in any mixed metal Mn/M clusters. Dc and ac magnetism studies revealed that \textbf{1} and \textbf{2} display dominant and entirely ferromagnetic exchange interactions leading to \(S_T\) values 23/2 and 12, respectively.

The isolation of complex \textbf{1} establishes the potential of the unexplored coordination chemistry of the triol btH\(_3\) to become a rich source of new compounds with novel crystal structures and interesting magnetism. In addition, the formation of the two supertetrahedral compounds \textbf{1} and \textbf{2} further demonstrates the capability of polyol-type ligands to stabilize various types of supertetrahedra appearing either in discrete form or as fragments of high nuclearity metal clusters. Although there have been quite a few studies in this area, additional investigations will definitely afford new types of molecular supertetrahedral aggregates exhibiting interesting properties. Further synthetic efforts involving the detailed exploration of the use of polyols, including btH\(_3\), in Mn and mixed metal Mn/M cluster chemistry are currently in progress.
